

Home Internet and Wi-Fi

Gateway DNS Resolution Failure

KB-TEST-901

Use this procedure when the customer's home internet connection is active but websites and applications fail to load because domain names cannot be resolved. Customers may report that Wi-Fi remains connected, the gateway shows an active internet connection, and direct access to known IP addresses works while ordinary website names fail. The issue may affect several devices at the same time and can result from stale gateway DNS state, an incorrect DNS configuration, or a provider-side DNS service problem. This procedure should not be used when the broadband connection itself is offline or when only one device is affected by a local configuration problem. The resolution steps for this issue are listed below and should be completed in order unless the observed condition requires escalation.

- 1 Confirm that the gateway has an active internet/WAN connection and determine whether multiple connected devices are affected.
- 2 Test whether the failure is limited to domain-name resolution rather than general internet connectivity.
- 3 Review the gateway's approved DNS configuration and refresh stale DNS or network state where supported.
- 4 Check for a current provider-side DNS incident when multiple devices continue to show the same resolution failure.
- 5 Verify that normal website and application access works on a known-good device before closing the case.
